# attachInterrupt()

## Description

# Digital Pins With Interrupts

The first parameter to attachInterrupt is an interrupt number. Normally you should use digitalPinToInterrupt(pin) to translate the actual digital pin to the specific interrupt number. For example, if you connect to pin 3, use digitalPinToInterrupt(3) as the first parameter to attachInterrupt.

#### **Board**

Uno, Nano, Mini, other 328-based Mega, Mega2560, MegaADK Micro, Leonardo, other 32u4-based Zero Due

#### **Digital Pins Usable For Interrupts**

2, 3 2, 3, 18, 19, 20, 21 0, 1, 2, 3, 7 all digital pins, except 4 all digital pins

#### Note

Inside the attached function, delay() won't work and the value returned by millis() will not increment. Serial data received while in the function may be lost. You should declare as volatile any variables that you modify within the attached function. See the section on ISRs below for more information.

### **Using Interrupts**

Interrupts are useful for making things happen automatically in microcontroller programs, and can help solve timing problems. Good tasks for using an interrupt may include reading a rotary encoder, or monitoring user input.

If you wanted to insure that a program always caught the pulses from a rotary encoder, so that it never misses a pulse, it would make it very tricky to write a program to do anything else, because the program would need to constantly poll the sensor lines for the encoder, in order to catch pulses when they occurred. Other sensors have a similar interface dynamic too, such as trying to read a sound sensor that is trying to catch a click, or an infrared slot sensor (photo-interrupter) trying to catch a coin drop. In all of these situations, using an interrupt can free the microcontroller to get some other work done while not missing the input.

## **About Interrupt Service Routines**

ISRs are special kinds of functions that have some unique limitations most other functions do not have. An ISR cannot have any parameters, and they shouldn't return anything.

Generally, an ISR should be as short and fast as possible. If your sketch uses multiple ISRs, only one can run at a time, other interrupts will be executed after the current one finishes in an order that depends on the priority they have. millis() relies on interrupts to count, so it will never increment inside an ISR. Since delay() requires interrupts to work, it will not work if called inside an ISR. micros() works initially, but will start behaving erratically after 1-2 ms. delayMicroseconds() does not use any counter, so it will work as normal.

Typically global variables are used to pass data between an ISR and the main program. To make sure variables shared between an ISR and the main program are updated correctly, declare them as volatile.

For more information on interrupts, see Nick Gammon's notes (http://gammon.com.au/interrupts).

### Syntax

 attachInterrupt(digitalPinToInterrupt(pin), ISR, mode);
 (recommended)

 attachInterrupt(interrupt, ISR, mode);
 (not recommended)

 attachInterrupt(pin, ISR, mode);
 (not recommended Arduino Due, Zero only)

#### **Parameters**

mode:

interrupt: the number of the interrupt (int)

pin: the pin number

(Arduino Due, Zero only)

ISR: the ISR to call when the interrupt occurs; this function must take no parameters and return nothing. This function is sometimes referred to as

an interrupt service routine. defines when the interrupt should be triggered. Four contstants are predefined as valid values:

- LOW to trigger the interrupt whenever the pin is low,
- CHANGE to trigger the interrupt whenever the pin changes value
- RISING to trigger when the pin goes from low to high,
- FALLING for when the pin goes from high to low.

The Due board allows also:

is high.

- HIGH to trigger the (Arduino Due, Zero only) interrupt whenever the pin

#### Returns

none

# Example

```
int pin = 13;
volatile int state = LOW;

void setup() {
    pinMode(pin, OUTPUT);
    attachInterrupt(digitalPinToInterrupt(pin), blink, CHANGE);
}

void loop() {
    digitalWrite(pin, state);
}

void blink() {
    state = !state;
}
```

[Get Code] (//www.arduino.cc/en/Reference/AttachInterrupt?action=sourceblock&num=1)

Normally you should use digitalPinToInterrupt(pin), rather than place interrupt an number directly into your sketch. The specific pins with interrupts, and their mapping to interrupt number varies on each type of board. Direct use of interrupt numbers may seem simple, but it can cause compatibility trouble when your sketch is run on a different board.

However, older sketches often have direct interrupt numbers. Often number 0 (for digital pin 2) or number 1 (for digital pin 3) were used. The table below shows the available interrupt pins on various boards.

Board	int.0	int.1	int.2	int.3	int.4	int.5	
Uno, Ethernet	2	3					
Mega2560	2	3	21	20	19	18	
32u4 based (e.g Leonardo, Micro)	3	2	0	1	7		
Due, Zero		(see below)					

The Arduino Due board has powerful interrupt capabilities that allows you to attach an interrupt function on all available pins. You can directly specify the pin number in attachInterrupt().

The Arduino Zero board allows you to attach an interrupt function on all available pins except for pin 4. You can directly specify the pin number in attachInterrupt().
